Measuring Economic Diversity: The Hachman Index, 2017

Authored by: DJ Benway, Research Analyst, Kem C. Gardner Policy Institute

The Hachman Index is a measure of economic diversity. Using indicators such as gross domestic product (GDP) or employment, the index measures the mix of industries present in a particular region relative to a (well-diversified) reference region. Hachman Index scores are normalized from 0 to 100. A higher score indicates more economic diversity, while a lower score indicates less economic diversity. The Hachman Index is often applied at the national level allowing for comparison between individual states. With reliable data, the index may also be applied to measure industrial distribution across counties as well. This brief examines the results of a Hachman Index analysis at the state and county level for 2017.

Utah Was One of the Most Diverse States in the Country in 2017

Utah and Missouri lead the nation in industrial diversity.1 According to a Hachman Index analysis using 2017 GDP data from the Bureau of Economic Analysis (BEA),2 Utah's industrial distribution is very similar to that of the U.S., and is one of the most diverse in the nation (see Figure 1). The Hachman Index is not an exact measure, and because Utah and Missouri have near identical scores—96.9 and 96.8, respectively—it is not definitive that Utah is more economically diverse than Missouri.

Utah is not only a clear leader in the nation, but is also a standout in the West. Arizona, Colorado, and California are the only other western states to have scores above 90. Utah's industrial composition is more diverse than the largest western states, including California. This despite Utah only having the 31st largest state GDP. California (1st), Colorado (19th), and Arizona (21st) all have larger economies than Utah.3

Urban Counties Have Diversified Economies While Rural Counties Are More Specialized

Davis, Salt Lake, Washington, and Weber counties are the most economically diverse within Utah. Salt Lake, Davis, and Weber counties include three of Utah's five metropolitan areas, and are three of the four largest counties in the state. Urban counties tend to have more diverse economies with a larger variety of economic opportunities and a wider range of industry sectors available to the population. Washington County contains the St. George metropolitan area and is the most populated county outside of the Wasatch Front.

Utah County and some of the more populated ring counties also have relatively diverse economies, with Hachman Index scores in the 70s (see Figure 2). A notable exception is Summit County, which has a high concentration of industries related to arts, entertainment, and recreation.6 This is due to the concentration of ski resorts and the resulting tourism-based economy around Park City.
Box Elder, Morgan, and Rich counties also have scores below 60, but are much less populated with smaller economies. However, their proximity to the more diversified ring counties may lead many residents to cross county borders for employment opportunities.

Natural resources like those found in the Uintah Basin can also create a concentration in specialized industries for counties. Duchesne, Emery, and Uintah counties all have very low index scores because they are heavily concentrated in the extractive industries. Other rural counties are agriculturally dominant (Beaver and Piute counties), while some are concentrated in accommodations (Garfield County), public administration (Daggett County), or other industries.

In Utah’s rural counties the population is significantly smaller than in the metropolitan counties, and their economies are more concentrated in specialized industries. While a more diversified industrial distribution could be beneficial to the long-term stability of these counties, some will remain strong due to intrinsic qualities of the county, e.g. geography, natural resources, or other non-replicable qualities unique to the area.

About the Hachman Index

The Hachman Index is the reciprocal sum, or mean location quotient, of the study area across all industries where the mean is generated by weighting the respective sectors’ location quotients’ by the sector shares in the region. The Hachman Index for a given time period is calculated as follows:

$$HI = \frac{1}{\left(\sum_i \left(\frac{ES_i}{ER_i}\right) \times (ES_i)\right)}$$

$ES_i$ is the share of the subject area employment in industry $i$.
$ER_i$ is the share of the reference region employment in industry $i$.

A Hachman Index score ranges from 0 to 100. A higher score indicates that the subject area’s industrial distribution more closely resembles that of the reference geography, and is therefore diverse. A lower score indicates a region is less diverse than the reference area, and more concentrated in fewer industries. Diversity in economic opportunities, as represented by a diverse set of industries, is generally considered a positive contributor to a region’s economic stability.

The Hachman Index is not without its shortcomings. For one, the subject area is contained within the reference region, i.e. Utah is included in the U.S., and so, to some degree, the subject area is being compared to itself. Another limitation of the Hachman Index is that it does not account for potential competitive advantages of a region. A region may have an advantage specializing in a specific industry, making a concentration in that industry economically justifiable over a more diversified economy.

Although diversification is usually considered a positive attribute for an economy, an increase in diversity may not be good for the labor market. As discussed in the 1995 Economic Report to the Governor, Utah had specialized in metal mining industries. In the mid-1980s Kennecott experienced major layoffs, which decreased its share of the overall Utah economy and therefore raised the measure of diversity in Utah. However, the effect on the labor market was negative, with lower employment levels. In essence, an increase in industrial diversity does not directly result in improvements for residents of the state, or imply economic growth.

The Hachman Index is also affected by the measures used. The value of the Hachman Index will be affected if broader measures are used. For example, an index calculated from employment by industry will behave differently over time from one calculated from GDP, due to changes in labor productivity that lead to increasing production using fewer employees.
Endnotes

1 As shown in Table 1: Hachman Index Scores for the States, 2017, Utah has a Hachman Index score 0.1 point higher than Missouri. However, the Hachman Index is not an exact measure and when comparing states the exact score is less important than the rank and range of scores across the country.

2 The Hachman Index was calculated using 2-digit North American Industry Classification System (NAICS) Sector Codes.

6 As defined by the North American Industry Classification System (NAICS) Sector 71: Arts, Entertainment, and Recreation.

7 A location quotient measures the relative concentration of an industry in one area compared to another. The Bureau of Labor Statistics defines it as a “ratio that compares the concentration of a resource or activity, such as employment, in a defined area to that of a larger area or base. For example, location quotients can be used to compare state employment by industry to that of the nation.” It is calculated by dividing an industry’s share of the total (employment, GDP, etc.) in the study region by its share in the reference region.

8 Hachman, 2002.
